

Prediction Using

BY:- AN

In today's life, diabetes has become a widespread and serious health problem due to modern lifestyle changes. The rise of sedentary habits, unhealthy diets, and increasing levels of stress have contributed to the growing prevalence of diabetes, which now affects people of all ages, including younger individuals. Diabetes is a chronic condition, characterized by the body's inability to properly regulate blood sugar levels, which can lead to severe complications such as heart disease, kidney failure, and vision loss if left untreated. Managing diabetes requires a combination of regular monitoring, dietary adjustments, and sometimes medication, which can be a significant burden on individuals and healthcare systems. Despite these challenges, recent advancements in healthcare technology have made managing diabetes more convenient and accessible, and prevention through healthy lifestyle choices is now

Machine learning is transforming the field of diabetes care by offering new ways to manage the disease. With the availability of large amounts of health data, machine learning can analyze key factors such as glucose levels, age, BMI, and family history to predict the risk of developing diabetes. In your project, applying algorithms like Logistic Regression, Gradient Boosting, and SVM enables you to model this risk accurately. Logistic Regression helps in understanding the direct relationship between health indicators and diabetes, while Random Forest and Gradient Boosting improve prediction accuracy by learning complex patterns in the data. SVM adds flexibility by handling non-linear relationships between features. These models, when evaluated through metrics such as accuracy and ROC-AUC, can effectively identify at-risk individuals early, allowing for timely medical intervention and personalized treatment plans, ultimately improving outcomes for patients in today's fast-paced, data-driven healthcare environment.

Let's start the project :-

```
In [1]: import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
import warnings
warnings.filterwarnings('ignore')
```

LOADING DATA & EDA

```
In [3]: df = pd.read_csv(r"C:\Users\ameet\Downloads\archive (12)\diabetes.csv")
df.head()
```

```
Out[3]:
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age	Outcome
0	6	148	72	35	0	33.6	0.627	50	1
1	1	85	66	29	0	26.6	0.351	31	0
2	8	183	64	0	0	23.3	0.672	32	1
3	1	89	66	23	94	28.1	0.167	21	0
4	0	137	40	35	168	43.1	2.288	33	1

```
In [4]: df.tail()
```

```
Out[4]:
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age	Outcome
763	10	101	76	48	180	32.9	0.171	63	0
764	2	122	70	27	0	36.8	0.340	27	0
765	5	121	72	23	112	26.2	0.245	30	0
766	1	126	60	0	0	30.1	0.349	47	1
767	1	93	70	31	0	30.4	0.315	23	0

```
In [5]: df.shape
```

```
Out[5]: (768, 9)
```

```
In [6]: df.ndim
```

```
Out[6]: 2
```

Rename the column using the mapping :-

```
In [8]: column_mapping = {'DiabetesPedigreeFunction': 'DPF'}
df.rename(columns=column_mapping, inplace=True)
```

```
In [9]: df.columns
```

```
Out[9]: Index(['Pregnancies', 'Glucose', 'BloodPressure', 'SkinThickness', 'Insulin',
             ..., 'BMI', 'DPF', 'Age', 'Outcome'],
             dtype='object')
```

```
In [10]: df.describe()
```

```
Out[10]:
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DPF	Age	Outcome
count	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000
